of this work toward this goal. Moreover, our work goes beyond the assessment of this area based target (34) to include other important variables to assess the potential contribution of restoration to biodiversity conservation. Our analysis could contribute to the post-2020 biodiversity framework, which is under negotiation through the Convention Biological Diversity to replace the current 2011–2020 Strategic Plan. Viewing restoration as a means to achieve certain goals and as an end in itself, restoration commitments should ideally identify the potential level of benefits that restoration can provide as criteria for identifying target areas. By doing so, the limited time and resources available to invest in restoration activities can be optimized and high levels of benefits could be provided even in cases where restoration is implemented in only a portion of the area committed (35). Thus, our findings could be used to optimize the implementation of restoration efforts in the context of the Aichi Target making better use of the limited time left before its expiration in 2020, and to guide the post-2020 restoration plans of the Convention on Biological Diversity.

The implementation of forest and landscape restoration commitments and targets also relies on many other socioenvironmental factors that were not included in this study, such as land tenure security, land disturbance factors, or legal instruments (5, 36), which demand attention when planning restoration at the local level. The benefit restoration could also be improved if complementary criteria are included in the analysis, such as the use of KBAs to identify areas where restoration could be more relevant to support the persistence of unique biodiversity groups (37). Recognizing the rights and livelihoods of local peoples is critically important when implementing restoration projects (38, 39). Other types of land-use changes geared toward electricity production (i.e., creating protected areas) or production (i.e., industrialized agriculture or forestry plantations) have often failed to recognize...

Brancalion et al., *Sci. Adv.* 2019, 5: eaaz2223 | 3 July 2019

**Fig. 1. Four critical questions to support decisions on forest and landscape restoration.** The questions are illustrated with examples of implementation under the two endpoints of the land sharing/sparing gradient.

predict (Fig. 1). In addition, the appropriateness of sharing/sparing is influenced by the biophysical characteristics of landscapes. For instance, mountainous regions may offer more opportunities for sparing, since marginal agricultural lands in steep slopes can be easily set aside to recover native ecosystems through natural regeneration (see Box 1). In regions dominated by intensive agriculture, policy instrument mandating or encouraging the recovery of native ecosystems in environmental fragile areas may foster sparing as well in small portions of the landscape (Rodrigues et al., 2011) while substantial increases in tree cover will rely on sharing approaches. Social actors' selection of restorative interventions and where in the agricultural landscape they are implemented will drive the outcomes of the future restored forest landscape.

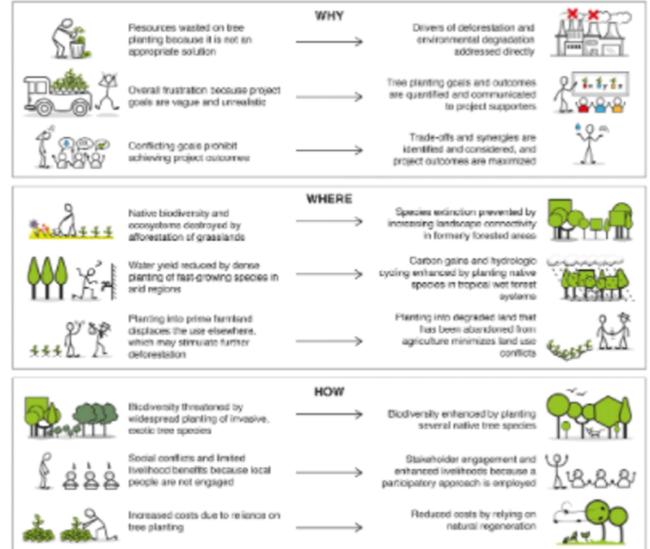

4. What are the main factors influencing restorative intervention outcomes? Finally, the selection among sharing/sparing approaches and their activities will be also related to factors that influence restoration outcomes. Configuration of the landscape to be restored, namely the proportion and spatial distribution of the remaining natural forests in the surrounding matrix, would determine these outcomes. For instance, ecological restoration should focus (at least on its first stages) on establishing new forested areas that provide a vegetation structure able to support water, soil-, and climate-related ecosystem services while providing habitat for wildlife (see 1), especially if total remaining native forest cover in the landscape is low (<30%; Banks-Leite et al., 2014). These areas may be better restored under sparing schemes while sharing schemes may be used in fragmented landscapes that still maintain some proportion of forest cover. These fragmented landscapes are very common in the tropics, where restorative interventions usually work at local scales and focus on particular landscape components (e.g., riparian or headwater areas) or functions (e.g., landscape connectivity for biodiversity), but allowing production (Melo et al., 2017). If there is very little remaining natural forest, FLR goals could increase forest extent and quality in the landscape (Hodgson et al., 2011), but also enhancing the landscape matrix through wildlife-friendly agriculture (Melo et al., 2013; Crespin

and García-Villalta, 2014). Both isolated trees or small foresting 'simple' crops and pasture increasing diversity, which agriculture may involve biodiversity learning from traditional farm organic agriculture, and restore as hedgerows to benefit wildlife (Rey-Lemay and Bullock, 2011) this could help a small scale bioculture are needed. Both approaches will determine land use for restoration.

At the same time, social is combined to understand land-use configurations. In a sparing can be socially controlled for people, opportunities should be also evaluated in the context of market, institutional and political factors, to be appropriately selected for different environmental and socioeconomic contexts and sustainable in time and (Brancalion et al., 2016). For instance, sparing policies may convey governments to solve initial financing and educational and cultural barriers for producers (mostly the local ones) to adopt more technologically advanced agricultural systems (Brancalion et al., 2012; Latawiec et al., 2014). Finally, land sharing/sparing decisions in FLR should also consider stakeholder preferences and livelihoods, while navigating conflicts among stakeholder interests and power asymmetries among them.

**Recommendations for forest and landscape restoration in the tropics**

FLR approaches will depend not only on degradation levels but also on the desired outcomes (Chazdon, 2008), working scales, and stakeholders' interests. Typically, FLR will need both land sharing and land sparing to fulfill its specific goals and achieve

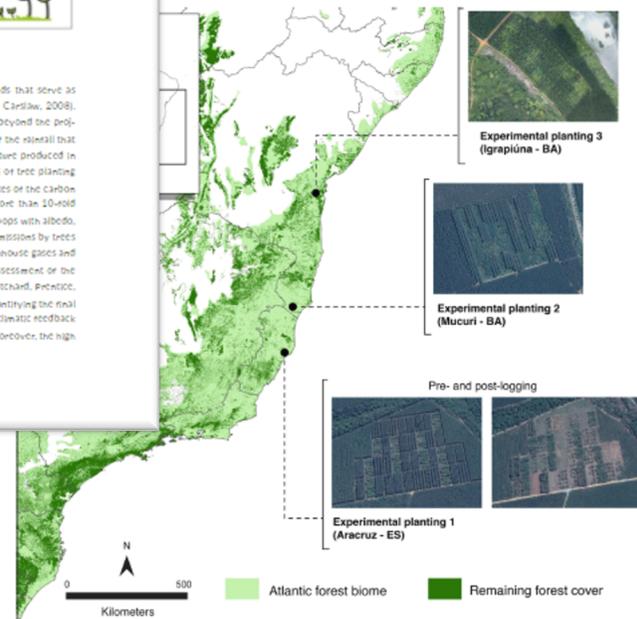

**FIGURE 1** Outcomes depend on why, where and how tree planting is done

Tree planting can be especially problematic in native non-forest ecosystems (Veldman et al., 2015), which are often overlooked by restoration and conservation policies. Tree planting can destroy the rich and unique biodiversity of ancient grasslands and savannas, in which many herbs and grasses are shade-intolerant and adapted to disturbances such as grazing and fires (Bond, 2016). Therefore, defining whether a target area was historically covered by forests is not a mere detail, but is one of the most important steps of a reforestation initiative (Figure 2).

Changes to the water cycle provide a good example of the complex effects of tree planting. At the catchment scale, increasing tree cover often reduces local water yield due to increased evapotranspiration (Folgo, Bezerra, Weiss, & Palmer, 2017), particularly in moist and regions (Farley, Jobbagy, & Jackson, 2005). At the regional scale, the added evapotranspiration or planted trees contributes to moisture redistribution (Elisson et al., 2017) and cloud formation

through the emission of volatile organic compounds that serve as moisture condensation nuclei (Spracklen, Bohn, & Carslaw, 2008). However, the additional rain may fall on areas far beyond the project boundaries. For instance, an important driver of the rainfall that sustains agriculture in Brazil results from the moisture produced in the Amazon (Lovejoy & Nobre, 2018). The impacts of tree planting on climate are even more uncertain. Global estimates of the carbon sequestration potential of forest regrowth vary more than 10-fold (Fuss et al., 2018), and there are multiple feedback loops with albedo, carbon dioxide concentration in the atmosphere, emissions by trees or volatile organic compounds that are potential greenhouse gases and changes in rainfall patterns that complicate the assessment of the overall climatic impacts of tree planting (Lewis, Mitchell, Prentice, Maslin, & Poole, 2015; Svingen et al., 2002). Quantifying the final balance of the multiple hydrological processes and climatic feedback is a major research challenge (Elisson et al., 2017). Moreover, the high

**FIGURE 1** Study sites within the Atlantic Forest of Brazil. Black lines in Atlantic Forest map indicate state boundaries. See Table S1 for biophysical and experimental site details. Other treatments were tested in these sites and can be seen in the images (e.g., eucalypt monocultures, intercropping eucalypts and native species in single lines), but these treatments are not discussed in this paper

which compensates farmers for the agricultural land use. Here, we established experimental plantings in three municipalities distributed across the eastern portion of the Atlantic Forest (Site 1: Aracruz-Espirito Santo, Site 2: Mucuri-Bahia, and Site 3: Igrapiúna-Bahia; Table S1; Figure 1). The experiments were established as a

# How to (seriously) read a scientific paper

Elisabeth Pain – Science  
Março de 2016

I start by reading the abstract. Then, I skim the introduction and flip through the article to look at the figures. I try to identify the most prominent one or two figures, and I really make sure I understand what's going on in them. Then, I read the conclusion/summary. Only when I have done that will I go back into the technical details to clarify any questions I might have.

- **Jesse Shanahan**, master's candidate in astronomy at Wesleyan University in Middletown, Connecticut

## Resumo – olhadela introdução - figuras

I also check if there are references that I may be interested in. Sometimes I am curious to see who in the field has—or more likely has not—been referenced, to see whether the authors are choosing to ignore certain aspects of the research. I often find that the supplementary figures actually offer the most curious and interesting results, especially if the results relate to parts of the field that the authors did not reference or if they are unclear or unhelpful to their interpretation of the overall story.

- **Gary McDowell**, postdoctoral fellow in developmental biology at Tufts University in Medford, Massachusetts, and visiting scholar at Boston College

## Figuras suplementares - resultados mais curiosos e interessantes

As editor-in-chief of *Science*, I have to read and comprehend papers outside of my field all the time. Generally, I start with the corresponding editors' summaries, which are meant for someone like me: a science generalist who is interested in everything but dives deeply only into one field. Next, I check to see if someone wrote a News article on the paper. Third, I check to see if there is a Perspective by another scientist. The main goal of a Perspective is to broaden the message of the paper, but often the authors do a great job of extracting the essence of the article for non-specialists at the same time.

Then I tackle the abstract, which has been written to broadly communicate to the readership of the journal. Finally, I move on to the paper itself, reading, in order, the intro, conclusions, scanning the figures, and then reading the paper through.

- **Marcia K. McNutt**, Editor-in-Chief, *Science journals*

## Does a (review) paper with good figures get more citations because of the figure?

In my opinion it does. Especially for review papers. A paper can benefit substantially from good visualizations, it makes the content more understandable and clear. Other scientists like to cite this work over a paper more difficult to understand.

Moreover, scientists have presentations in meetings and seminars all the time. In the introduction, the best available figure in their field of work is used quite often. This will encourage people in the audience to write down the reference. I bet they will cite the original paper next time they write something related to the subject. (of course the research has to be good).

I'm very curious to hear your opinion about this.

**Cientistas preferem citar texto mais claros de entender e usam as figuras em apresentações e conferências**

Serkan Erdoğan  
added an answer

February 19, 2014

it does, I completely agree with you! For instance, when I start to read a new paper, I immediately observe the figures, and I am very careful on preparing of figures of my papers too. If figures are painstaking, smooth and clear, paper can be more attractive for readers..

**Antes de ler todo o artigo vê as figuras**

Jana Kusch  
added an answer

October 17, 2012

I totally agree with you all, about the papers and also about the oral presentations on conferences.

It seems we are an "eye species". You can watch that in a very simple form if students learn a complicate issue or if somebody explains a complex fact, they take a pen and start painting in parallel.

Thus, I think an illustration is not just helpful for the readers but also for the illustrator himself/herself to bring the message to the point. The better the illustrator knows about all details, the better is the illustration.

**“Entendeu ou quer que eu desenhe?”**

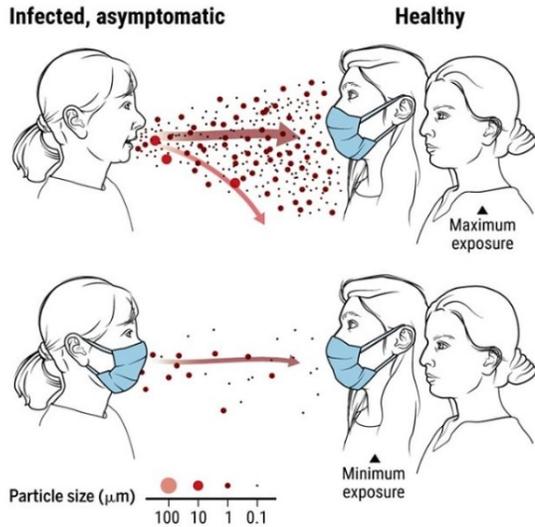

Pedro M. Matos

## How European countries generated electricity in 2018

Germany is the largest energy producing country in Europe. It generates the most renewable and conventional thermal energy, representing 31% and 36% of its overall production respectively. France is the second largest energy European producer and by far the largest nuclear energy provider: 71% of its production is based on nuclear fusion to generate heat.

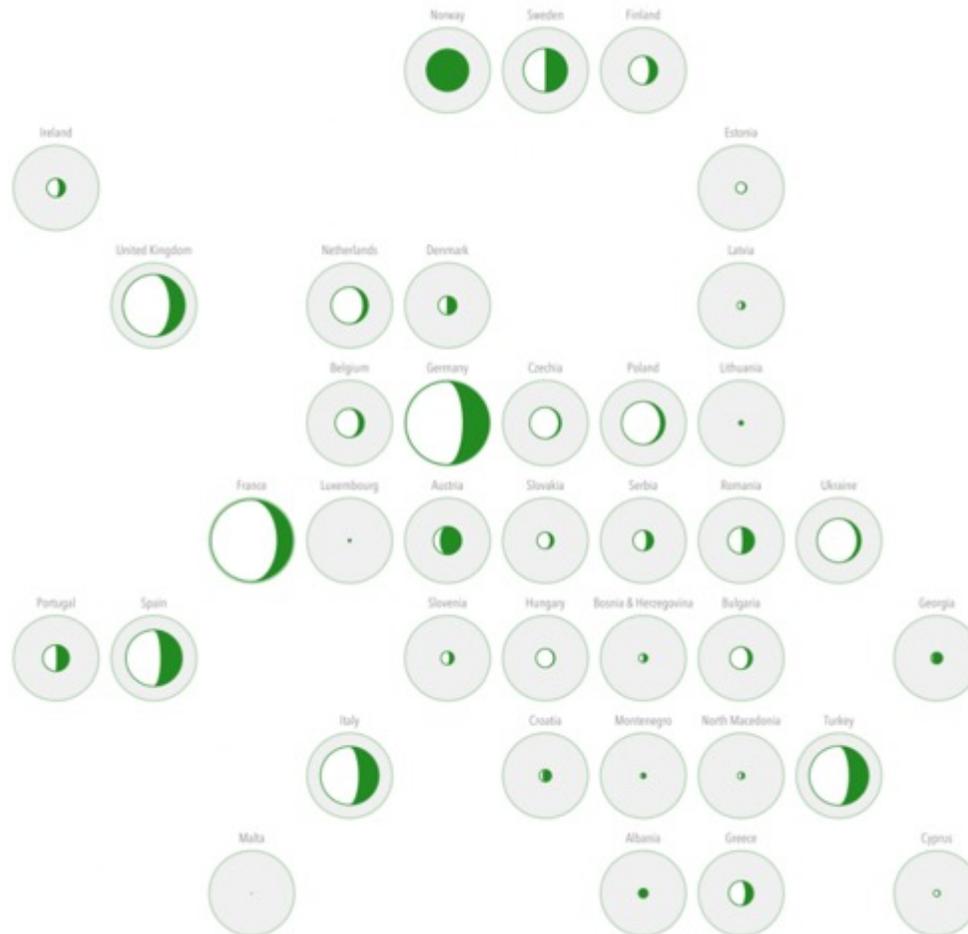

Renewable energy is energy that comes from resources that are naturally replenished such as sunlight, wind, water, and geothermal heat. Unlike fossil fuels, such as oil, natural gas and coal, or nuclear power sources such as uranium and plutonium, renewable energy regenerates naturally in a short period of time.

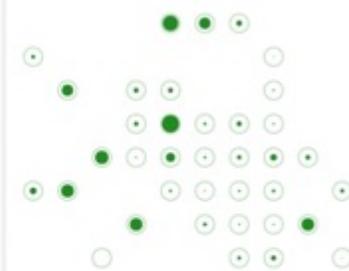

Norway had an electricity production almost entirely made up of renewable energy (98%). This makes Norway the second largest producer of this energy type in Europe. Interestingly, most of the renewable energy is produced by hydro power that take up 92% and only 3% by wind. In contrast, twelve European countries were reported to produce less than 20% of their energy with renewable resources: Malta (0%), Hungary (1%), Estonia (0%), Czechia (1%), Cyprus (0%), Ukraine (0%), Poland (10%), Netherlands (17%), Bulgaria (17%), Belgium (0%), Slovakia (0%), and France (0%).

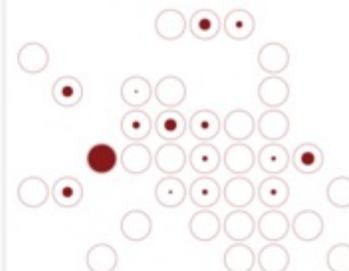

Note: Energy production is mapped to the area of the circles.
